$$= n(2a + (n-1)d)/2$$

The first term in the series is a , and the last one is $a + (n-1)d$, so we can say the sum of the series is the

first term plus the last term multiplied by the number of terms divided by 2.

$(a + b)^n = a^n + (n C 1)a^{n-1}b + (n C 2)a^{n-2}b^2 + \dots + (n C n-1)ab^{n-1} + b^n$. Example.

Expand $(4 + 2x)^6$

in ascending powers of x up to the term in x^3 .

This means use the Binomial theorem to expand the terms in the brackets, but only go as high as x^3 . So to find the answer we substitute 4 for a in the Binomial theorem and $2x$ for b :

So if n is composite (say $r \cdot s$ with $1 < s$

File Type PDF 1

S Devoir N 2

$< n$), then 2^{n-1} is also composite (because it is divisible by 2^{s-1}).

Notice that we can say more: suppose $n > 1$. Since $x-1$ divides x^{n-1} , for the latter to be prime the former must be one. This gives the following. Corollary. Let a and n be integers

greater than one. If
a $n-1$ is prime, then
a is 2 and n is
prime.

If 2^{n-1} is prime,
then so is n -
